## 1. Concept layout of transcritical system with ETE

The system sensors for the ETE:

CODE	Nomenclature	DEFINITION	Түре	DESCRIPTION
	VM-SC-SUB	Electronic Expansion Valve of	Component	EEV that expand a quote part of the total mass flow, come from the GC,
		ETE		from the GC pressure to the ETE evap. Pressure. It works to maintain the
				SH at the outside of the P.H.E. ETE, before the COMPR. ETE. PS 120bar.
	P.H.E. ETE	Plate Heat Exchanger of ETE	Component	Heat exchanger dedicated to the sub-cooling of the mass flow come from
				GC. PS 120bar.
	COMPR. ETE	Compressor of ETE	Component	Dedicated compressor with inverter for the ETE with dedicated suction.
				It works at very high-pressure level (40-45 bar). Same compressor type
				of the other one of the pack. PS 100bar at suction.
	VM-SUB	2-Way Motorized Valve	Component	Positioned above the EEV ETE, the function is below described.
		OR		THE PRESENCE OR NOT OF THE MOTOR AFFECT THE EEV STAND-BY PARAMETER
		Only ball valve		
	ST-Gc	Temperature at the outside of GC	Temp. probe	Temperature at the outside of the gas cooler. It gives the consent to the 2-way motorized valve to open and to the EEV controller. Is the same temp. probe of HPV valve.
	ST-OUT-SUB	Temperature at the outside of ETE	Temp. probe	Temperature at the outside of the ETE and at the inlet of the HPV (only read).

### **ETE - Commissioning with Danfoss**

### 2. About controller

For the ETE, two additional controllers are located inside the pack electrical board:

- AK-PC781A: to manage the compressor of the ETE

- EKE 1C: superheat controller of the EEV of the ETE

Pag. 5/18

### 2.1 Logic of ETE activation

The ETE will activate in summer and mid-season periods in order to subcooling the CO2 refrigerant at the inlet of the Transcritical valve. The subcooling effect permits to use of the CO2 transcritical system when the external temperature is above 40 °C, reducing significantly the amount of the flash gas product by the system.

From controller point of view, the activation of ETE will be if the following conditions are satisfied:

- 1. Selector **SUB** of the **ETE REGULATION** in pack electrical board in **ON**, the KERS is activated:
  - a. AKPC781A is in ON from digital input and it is ready for regulation in pressure
  - b. The light HERS in front of electrical board switches on
- 2. Selector of the COMPRESSOR C4A SUBCOOLER in pack electrical board in AUTO;
- 3. Selector SVSU of the SUBCOOLER 2 WAY VALVES in pack electrical board in ON (it refers to HOSU light); (IF THE MOTOR IS PRESENT)

- 4. IF:
- a. At least 1 MT compressor is running (relè KM14.2 active);
- b. Inverter of the ETE compressor is in NO alarm state ad ETE compressor in NO alarm state (relè KA4AT active);
- c. T OUT GC (ST-GC and ST-BK-GC) is above the generic thermostat n° 5 cut in temp. (general thermostat function in the AKPC782A, main pack controller – check in the wiring diagram the correct number of general thermostat function configurated).
- → KOSC is activated and the light HOSC in front of electrical board switches on.

#### When KOSC is active:

5. **IF THE MOTOR IS PRESENT** the VM-SUB (2-Way Motorized Valve managed by K3WSU) open (HOVSU light switches on);

6. it is enabled from digital input the regulation of EVD. The VM-SC-SUB (ETE EEV) starts to open and to check the superheat after the P.H.E. ETE;

### 2.2 Oil system

The new oil system consists of:

- Oil separator with integrated reserve
- Oil Reserve

The whole oil system has security pressure of 120bar and follows the gas cooler pressure. Stainless steel AISI 304L is used for piping.

The separator recovers the oil present in the refrigerant and through the connection between the separator and the reserve, the oil level is distributed equally between the two volumes.

In the lower half of the reserve there is the oil level sensor (3) with the only purpose to highlight a low level of oil in the system.

The alarm is visible in the AK-PC782A.

For more info refer to document SE-TS0050R00.

## 3. Before the commissioning

Check the following parameters/components before the commissioning of the ETE.

- 1. Charge the pack of oil following the SE-TS050R00 guideline
- 2. Check if the AKPC781A end the EKE 1C are visible from System Manager AK-SM8XX
- 3. Check the limit of the ETE compressor inverter (in inverter as well as in 781A):
  - Min = 25 Hz
  - Max 60 Hz
- 4. Check the MOP value in the EKE 1C:
  - N011 = 18 °C
- 5. Check the Superheat parameters in the EKE 1C:
  - N009 = 11 K (Super heat max)
  - N010 = 6 K (Super heat min)
- 6. To activate the ETE, check the position of the following shut off valves:
  - Open shut off valves 1 and 3, close 2
  - Open 4 and 5
  - Check the shut off valve on teklab of the ETE compressor

## 3.1 Safety element in the ETE system

Between the shut off valves 4 and 5 there is the solenoids valve SV-RLV.

The SV-RLV is activated if there are some of the following situation:

- Leakage from non-return valve of ETE compressor (when compressor is not running)
- Malfunction of the ETE EEV (VM-SC-SUB)

This valve will be excited when one of the following conditions is satisfied:

- 1. ETE compressor and/or ETE inverter are in ALLARM
- 2. T OUT GC (ST-Sd) is BELOW the generic thermostat n° 5 cut out temp. (\*)

AND (all satisfied):

- 3. the pressure on the ETE compressor suction (Sp-Po-SUB transducer) is above pressure switch function n.1 (\*) in AKPC781A (set: ON>40bar / OFF<36bar)
- 4. at least 1 MT compressor is running
- 5. KERS relay is active (Selector of SUB in ON)

(\*) check in wiring diagram the correct number of pressure switch function and generic thermostat configurated.

### **ETE - Commissioning with Danfoss**

## 4. Commissioning

To star the ETE technology the following actions must be done.

Remember that the running of ETE is strongly related to the external condition. In general, it is worthy to star the ETE when temperature at outlet of the gas cooler is above the ETE starting set (default = 27 °C).

If the external conditions are enough, the commissioning can start.

- 1. Selector **SUB** of the **ETE REGULATION** in rack electrical board in **ON**;
- 2. Selector of the COMPRESSOR Cx4A SUBCOOLER in rack electrical board in AUTO;
- 3. Selector SVSU of the SUBCOOLER 2 WAY VALVES in rack electrical board in ON;
- 4. Check the parameter in the AKPC781A (Suction group  $\rightarrow$  Po reference):
  - Setpoint = 10 °C
- 5. Check the generic thermostat  $n^{\circ}$  5 on the AKPC782A through service tool (General purpose  $\rightarrow$  Thermostat  $\rightarrow$  Activation subc. Exch.):
  - generic thermostat n° 5 cut in temp.= about 27 °C
  - generic thermostat n° 5 cut out temp.= about 25 °C

(the values could change from pack to pack and it depends about the size of the ETE compressor and the city of installation)

6. HCVSU switch off and HOVSU on:

*Pag.* **17/18** 

Date: 14/05/2021

## SYSTEM ENGINEERING

Project: Insert PJ

### **ETE - Commissioning with Danfoss**

- 7. Verify the opening of the EEV of ETE: it starts to regulate to maintain the SH at 11K.
- 8. Due to the increasing pressure inside the suction pipe, the ETE compressor will start running.
- 9. Check that the *ST-OUT-SUB* is visible from System Manager (therm.function 1 in AK-PC781A *check in electrical scheme the correct number of thermostatic function configurated*).
- 10. The ETE system should run and in order to see the subcooling effect:
  - ST-OUT-SUB (compared it with the T out Gas Cooler. The difference of the two probes is the subcooling delta)
  - Flash Gas % opening (in reduction)
  - Main liquid receiver pressure (stable)
- 11. Check the status of main rack in order to be sure that system has achieve the balance (main liquid receiver, HPV valve, Flash Gas valve etc..)
- 12. AS EXAMPLE, if properly commissioned, typical situation in summer period could be:
  - (ST-Gc) T out GC = 39 °C
  - (SP-GC) p GC = 95bar
  - (ST-OUT-SUB) T out ETE = 25 °C
  - Flash Gas % = 7%
  - (SP-REC) p main liquid receiver = about 36bar
